Binomial

Suppose we repeat n Bernoulli experiments, independently and with constant probability of success p . Define X as the random variable that counts the total number of successes. Then X takes possible values in the set $D = \{0, 1, \dots, n\}$.

To Calculate the probability function we observe that, in order to obtain exactly x successes, we need exactly $n - x$ failures. There are $\binom{n}{x}$ equally likely ways for this to happen. Thus,

$$f_x(x) = \begin{cases} \binom{n}{x} p^x (1-p)^{n-x} & | x \geq 0 \\ 0 & | \text{else} \end{cases}$$

Notice that

$$\sum_{x=0}^n f_x(x) = \sum_{x=0}^n \binom{n}{x} p^x q^{n-x} = (p+q)^n = 1$$

Notated: $X \sim \text{Bin}(n, p)$

Example

The Giants need to win at least four of the remaining six games to make the playoffs. Given a record of 27-27 what is the probability they succeed?

We assume $p = 0.5$ and that X is the number of wins in the next six games. Then $X \sim \text{Bin}(6, 0.5)$. We want

$$Pr(X \geq 4) = Pr(X = 4) + Pr(X = 5) + Pr(X = 6) \tag{1}$$

$$= \left(\frac{1}{2}\right)^6 \left(\binom{6}{4} + \binom{6}{5} + \binom{6}{6} \right) \tag{2}$$

$$= \frac{11}{32} \tag{3}$$

Hypergeometric

A hypergeometric experiment is like multiple Bernoulli trials except there is dependence between the trials.

Suppose a box contains A red balls and B blue balls. n balls are drawn without replacement from the box. A random variable X is equal to the number of red balls drawn. $X \leq \min\{n, A\}$. Also the sample has $n - X$ blue balls, thus, $n - X \leq B$, then

$$\max\{0, n - B\} \leq X \leq \min\{n, A\}$$

Then

$$Pr(X = x) = \frac{\binom{A}{x} \binom{B}{n-x}}{\binom{A+B}{n}}$$

Notated: $X \sim Hyper(n, A, B)$

Example

The probability function is given as

$$f_x(x) = Pr(X = x), \quad \max\{0, n - B\} \leq x \leq \min\{n, A\}$$

We have patients suffering from depression. 34 recieved a placebo. Of those, 10 had no relapse, and 24 had a relapse.

Suppose we take a sample of patients with $n = 11$. Let $X = \#$ of successes. Then $A = 10$ and $B = 24$.

$$0 = \max\{0, 11 - 24\} \leq X \leq \min\{11, 10\} = 10$$

and

$$f_x(x) = \frac{\binom{10}{x} \binom{24}{11-x}}{\binom{34}{11}}, x = 0, \dots, 10$$

Negative Binomial

A sequence of Bernoulli trials with probability of success p , that stops after a given number of successes is reached. A normal Binomial stops after n trials, a negative Binomial has n as a random variable.

$$Pr(X = x) = Pr(x \text{ failures before } r \text{ successes occur}) \quad (4)$$

$$= Pr(x \text{ failures and } r-1 \text{ successes in } x+r-1 \text{ trials}) \times \quad (5)$$

$$Pr(\text{one success in the } (x+r)-1 \text{ th trial}) = \binom{x+r-1}{x} q^x p^{x+r-1-x} \times p \quad (6)$$

$$= \binom{x+r-1}{x} q^x p^r, x = 0, 1, \dots \quad (7)$$

Notated: $X \sim NegBin(p, r)$

Example

To pass a quiz you need five correct answers. The system provides a new question, until you reach the fifth correct answer. Your grade is $(5/\text{attempts}) \times 100$. What is the probability that you will score 50% assuming you are guessing the correct answers?

To score 50% you need 5 correct answers in 10 attempts. Assume you have a 50% chance of guessing the correct answer.

$$x = 5 \quad (8)$$

$$r = 5 \quad (9)$$

$$\binom{9}{5} \frac{1}{2} \frac{1}{2} \quad (10)$$

$$= 0.1230469 \quad (11)$$

Geometric

A Geometric experiment is a negative binomial with $r = 1$.

Therefore, the formula is

$$f_x(x) = pq^x, \quad x = 0, 1, \dots$$

This works because

$$\sum_{x=0}^{\infty} f_x(x) = \sum_{x=0}^{\infty} pq^x = p \sum_{x=0}^{\infty} q^x = p \left(\frac{1}{1-q} \right) = \frac{p}{p} = 1$$

It is notated $X \sim Gep(p)$

Memory Loss Property

Consider $X \sim Geo(p)$

$$Pr(X \geq x) = 1 - Pr(X < x) = 1 - Pr(X \leq x - 1) \quad (12)$$

$$= 1 - \sum_{i=0}^{x-1} q^i p = 1 - p \frac{1 - q^x}{1 - q} = q^x \quad (13)$$

Suppose $X \geq t$, what is the probability that $X = t + h, h > 0$?

$$Pr(X = t + h | X \geq t) = \frac{Pr(X = t + h)}{Pr(X \geq t)} \quad (14)$$

$$= \frac{pq^{t+h}}{q^t} = pq^h = Pr(X = h) \quad (15)$$

The geometric "forgets" that there have been t attempts or more. Past attempts do not influence the probability of future attempts.

Another example is radioactive decay, each individual particle has a geometric probability function.

Poisson

A Poisson random variable counts the number of occurrences of an event. It can therefore take any possible positive integer.

Some examples: # of new Covid positives, # of tweets, # of requests, etc.

The probability function of a Poisson can be obtained as the limit of the probability function of a binomial where the number of trials go to infinity. This results in

$$f_x(x) = \frac{e^{-\lambda} \lambda^x}{x!}, x = 0, 1, 2, \dots$$

Here λ is a parameter that determines the intensity of the process of occurrences per unit time.

Is $f_x(x)$ a probability function? $f_x(x) > 0, \forall x$. Then

$$\sum_{x=0}^{\infty} f_x(x) = \sum_{x=0}^{\infty} \frac{e^{-\lambda} \lambda^x}{x!} = e^{-\lambda} \sum_{x=0}^{\infty} \frac{\lambda^x}{x!} = e^{-\lambda} e^{\lambda} = 1$$
